ABSTRACT

In the design of culverts for fish passage, knowing the water depth is important as it relates to roughness. Engineers currently select roughness coefficients, such as Manning's n , from a table that has been calculated from full flow conditions for culvert design. It is known from previous investigations that Manning's n varies with depth. According to Lang *et al.* (2004), flows at half depth or lower are the typical flows that fish will encounter. If the designer is using constant Manning's roughness coefficients for full flow, a substantial error in calculating water depth could result (Lang *et al.* 2004). The objective of this research is to develop an equation to predict water depth inside of partially filled circular culverts independently from the Manning's equation.

A new equation to predict depth (d) for a circular culvert, based on discharge (Q), slope (S), diameter (D), gravity (g), and absolute material roughness (K_s), has been developed. The new equation reduces the absolute mean error in calculating water depth by 37% compared to the previously published data. Data from five studies representing partially filled culvert conditions in concrete, clay, corrugated metal, PVC, and HDPE circular pipes with slopes and diameters ranging from 0.05 – 4% and 4 – 36 inches, respectively, were used in this study to establish the new equation.

The new equation allows for the explicit solution of depth while the Manning's equation requires an implicit solution. The iterative solver used (Excel Goal-Seek) did not find a viable solution for predicted depth using the Manning's equation in 29% of the cases reported in the literature. The new equation predicts depth more frequently and with greater accuracy than the Manning's equation for the data analyzed; and is therefore, a more consistent method when used to design and assess culverts for fish passage.

Dedication

To my family: Heather, Steven Jr., and Joseph.

Acknowledgements

First and foremost I would like to thank my wife Heather, without her continued support, love, and encouragement this would not have been possible for me. Secondly, I would like to thank my two sons, Steven and Joseph, for understanding that I was not always available for playtime.

I would like to thank Dr. Tritico for his enthusiasm, guidance, advice, support, and passion for Water Resources Engineering.

I would also like to thank my brother Sam for his ingenious programming skills on writing the Macros used to interpret and evaluate my data (Appendix I).

Lastly, I would like to thank The Center for Transportation and Materials Science Engineering (CTME) for providing funding; YSU for all the wonderful years I have experienced here; the Civil Engineering Department for the education they have provided me; and Linda Adovasio for always knowing or finding the answers or resources for all my questions throughout the years.

1.0 Introduction

Throughout the United States, there are millions of miles of roads. Often these roads cross streams negatively affecting the aquatic ecology (Dryden and Jessop 1974). Engineers design and oversee the construction of culverts that facilitate stream flows beneath these roads. Historically, adverse impacts on fish and other aquatic organisms were not considered a significant design factor for culvert design (Richmond *et al.* 2007). Engineers unknowingly disrupted stream ecology or gave little regard to the disturbance that culverts create. Fish use streams for migration purposes, spawning, and feeding throughout their lives (Lang *et al.* 2004). It is now known that many of these culverts are barriers to fish passage because the hydraulic conditions of the culverts strongly influence passage success (Lang *et al.* 2004). Culvert design that minimizes the conditions which create barriers for fish passage has become an important ecological issue. The purpose of this research is to develop an equation to predict water depth in a circular culvert independent of the Manning's equation that will aid in the design of culverts to facilitate fish passage.

Richmond *et al.* (2007) state that according to the American Iron and Steel Institute (1993) "typically, studies of culvert flow have focused on bulk hydraulic properties pertinent to culvert performance such as head–discharge relationships, mean velocity, sediment and debris transport, and energy budgets." One aspect of culvert design that is often overlooked is the hydraulic properties under partially filled flow conditions. Engineers currently select roughness coefficients from a table that has been calculated from full flow conditions for culvert design. Flows at half depth or lower are often the typical flows that fish will encounter during their migration. According to Lang

et al. (2004) roughness values change with depth and are expected to be much higher during typical fish migration flows resulting in lower occupied velocities. Webb *et al.* (1993) have shown that as velocity increases, drag on the fish increases creating hydraulic conditions that may lead to a fish passage barrier.

Lang *et al.* (2004) further states that table *n* (Manning's roughness coefficient *n*) values used in hydraulic modeling analysis for fish passage during the design phase of a culvert would introduce a substantial amount of conservatism; they conclude that "literature *n*-values tend to overestimate velocities, and underestimate water depth." They further state that "a need exists for developing roughness coefficients for various culvert materials at flows common to fish passage." This research seeks to improve upon the estimation of water depth in partially filled circular culverts.

2.0 Literature Review

2.1 Culverts as Ecological Impediment of Fish Passage

According to Kane and Wollen (1985), culverts are simple hydraulic structures designed for peak discharge that can cause serious problems for fish migration. Some of the problems or barriers encountered for migrating species through culverts are increased velocity, vertical barriers, and shallow water depths (Fitch 1995). Many fish, and more importantly juvenile fish, will not migrate upstream through culverts exhibiting increased water velocities (Barber and Downs 1996) whereas the proper design of a culvert will not produce water velocities that surpass the swimming abilities of fish (Behlke *et al.* 1991). Culvert design for fish passage must take into consideration the hydraulic conditions created by the culvert's size, slope, material, depth, and velocity (Bates 1994); however, culvert design criteria have been based on a limited number of studies (Kane and Wollen 1985).

Fish passage through culverts has been recognized as problem or concern for over a half century (McKinley and Webb 1956; Anderson and Bryant 1980). Since then, many remedies have been constructed or implemented to improve fish passage. According to Gebhards and Fisher (1972), some remedies implemented have been gradient choice, length of the culvert, baffles, multiple culverts, fishways, downstream controls, depth control, and decreased water velocity. According to Lang *et al.* (2004), water velocity and depth are the critical components in culvert design for fish passage and are currently calculated from full flow Manning's n values. Consequently, research is needed to determine water depths that allow fish passage independently from Manning's equation.

2.2 Manning's Roughness Coefficient

In the design of culverts and open channels, the Manning's Formula is the most widely accepted equation to calculate discharge or water depth (Equation 1; Chow 1959; Khan 1986).

$$Equation \ (1): \quad Q = \frac{1.486}{n} (R)^{\frac{2}{3}} (S)^{\frac{1}{2}} (A)$$

The variables in the formula are denoted as discharge (Q , ft³/s), cross-sectional area (A , ft²), hydraulic radius (R , ft) which is the ratio of cross-sectional area to wetted perimeter, slope (S , ft/ft) of the energy grade line, Manning's roughness coefficient n , and the numerical coefficient 1.486 is the conversion factor from metric to English standard units (Chow 1959).

2.3 Parameters Affecting Manning's Roughness Coefficient

There are geometric and hydraulic parameters that are understood to affect the value for Manning's roughness coefficient n for pipes designed at full flow (Lang *et al.* 2004; American Concrete Pipe Association 2007). Such geometric parameters include pipe diameter, pipe material, shape, seams or joints, corrugations and in situ conditions such as pipe slope. For instance, seams and joints that are not properly aligned and the number of joints could affect the roughness value (Pomeroy 1967, Mays 2005). Hydraulic parameters that affect Manning's roughness are velocity, flow rate, depth of flow, hydraulic radius, and slope of the energy grade line (Chow 1959; Khan 1986, Bloodgood and Bell 1961).

2.3.1 Geometric Parameters

The three most common materials used in culvert pipe are concrete (pre-cast, reinforced and non-reinforced), corrugated aluminum (CAP), and corrugated steel (CSP) (Normann 2005); but other materials are used as well, for example, vitrified clay (VCP), galvanized steel, and corrugated plastics (CPP), such as high density polyethylene (HDPE) (Ohio Department of Transportation 2007). According to Normann (2005) different materials have unique or distinct roughness properties but “culverts may also be lined with other materials to inhibit corrosion and abrasion, or to reduce hydraulic resistance”. The unique properties of materials that line culverts may also affect roughness values.

The culvert shape and slope can have numerous variations. The most common shapes include circular, box, arch, pipe arch, metal box, and elliptical (Normann 2005). This thesis investigates circular culvert pipe. Culvert diameters can range from four inches to several feet (Ead *et al.* 2002) and according to Straub and Morris (1951) the n value increases with an increase in pipe diameter of the same material.

2.3.2 Hydraulic Parameters

Manning’s roughness coefficient n is a function of velocity, which in turn is a function of the various hydraulic parameters found in the Manning’s equation (Chow 1959; Khan 1986). Velocity is a function of discharge, slope, and cross-sectional area (Chow 1959). The installed slope of a culvert may vary generally from zero to about five percent (Ead *et al.* 2002) affecting the velocity. The shape of the conduit will affect the depth of flow, cross-sectional area, and wetted perimeter causing the value of the

hydraulic radius to change. As discharge decreases, roughness becomes variable (Chow 1959).

2.4 Previous Investigations

There have been eight (known to the author) previous investigations of Manning's n under partial flow conditions for circular culvert or sewer pipe. A gap in the historical data from 1970 to 2009 was discovered while researching Manning's n for this literature review, which identifies a need for an updated study but limits the author to data and results which are forty years and older. The known investigations include Yarnell and Woodward (1920), Wilcox (1924), Camp (1946), Straub and Morris (1951), Cosens (1954), Neale and Price (1964), Pomeroy (1967), and Cox, Thornton and Beeby (2009). Reviews of these studies followed by a plot of their respective data or trend lines are presented. For all investigative graphs, the y-axis is the relative depth and the x- axis is the relative roughness. Relative depth (d/D) is the ratio of depth to diameter; whereas, the relative roughness (n/n_f) is the ratio of partial roughness to full flow roughness (n_f).

In recent years, pipe manufacturers have commissioned numerous studies but these data have not been published in journals or manuals. In an effort to obtain test data, manufacturers were contacted several times to request data, but no response was received. Since most research has focused on full flow conditions it is not likely that these experiments contain data on partial flows.

2.4.1 Yarnell and Woodward (1920)

Yarnell and Woodward (1920) produced a significant amount of data for culverts experiencing partial flow conditions (plotted as Figure 1, see Appendix A for Legend).

They performed their research on clay and concrete drain tile ranging in diameter from four to twelve inches with slopes from 0.05 to 1.5%. The data contain partial flow conditions ranging from approximately 25% capacity to full (100%) flow. They noted that velocity was not constant at half and at full flows. The hydraulic radius of circular culverts at full depth and half depth are equal. Because the hydraulic radius is the same at half and full flow, the only way to alter the velocity is through a change in the n value. It is important to note that this study was not based on Manning's roughness but on the Kutter n and the Chezy C.

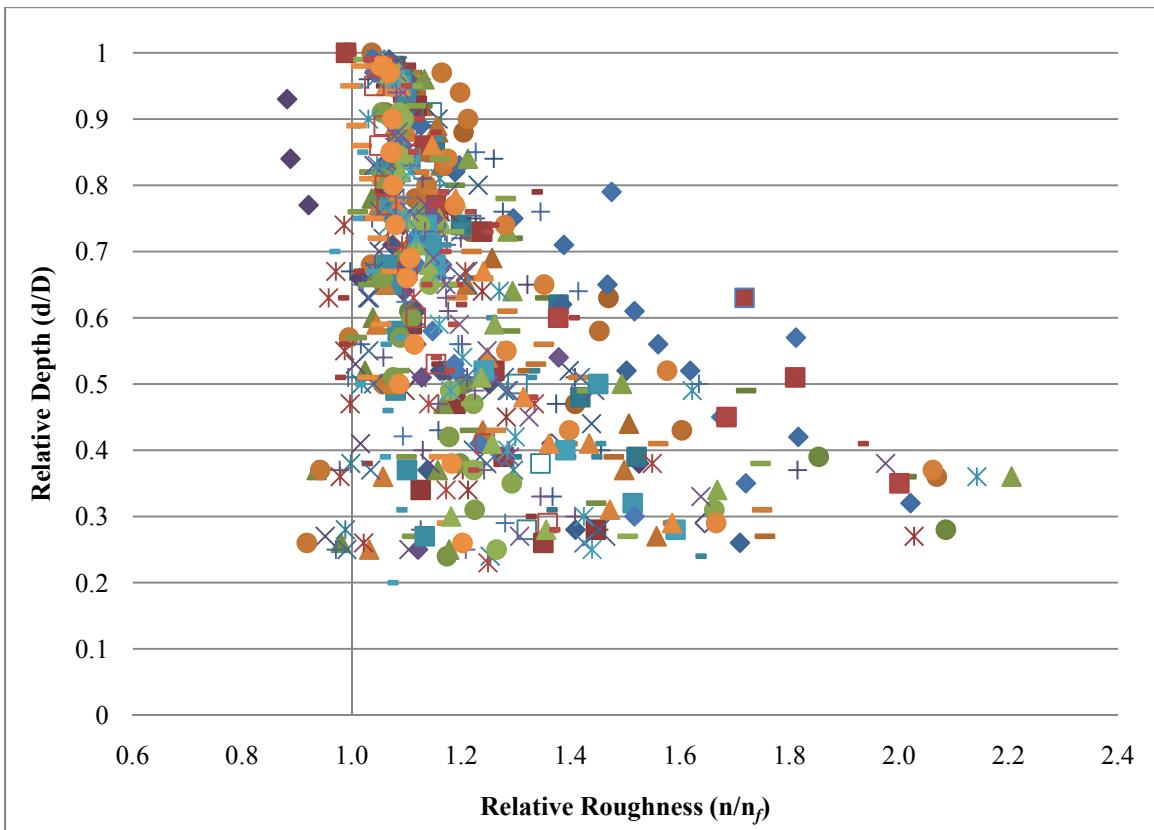

Figure 1: Experimental Data from Yarnell & Woodward (1920) (Legend in Appendix A). Decreasing Relative Depth increases the range in Relative Roughness values.

2.4.2 Wilcox (1924)

Wilcox (1924) examined eight inch asbestos concrete and vitrified clay pipe (VCP) with slopes from 0.5 to 4%. The pipes were analyzed at different discharges and depths of flow. It was found that the VCP had higher velocities than the asbestos cement under identical conditions. While Wilcox's primary finding was that material composition affects the n value under partial flow conditions, he also found that the velocity varied with depth indicating that relative roughness values become larger as depth is decreased. A plot of his data is shown in Figure 2.

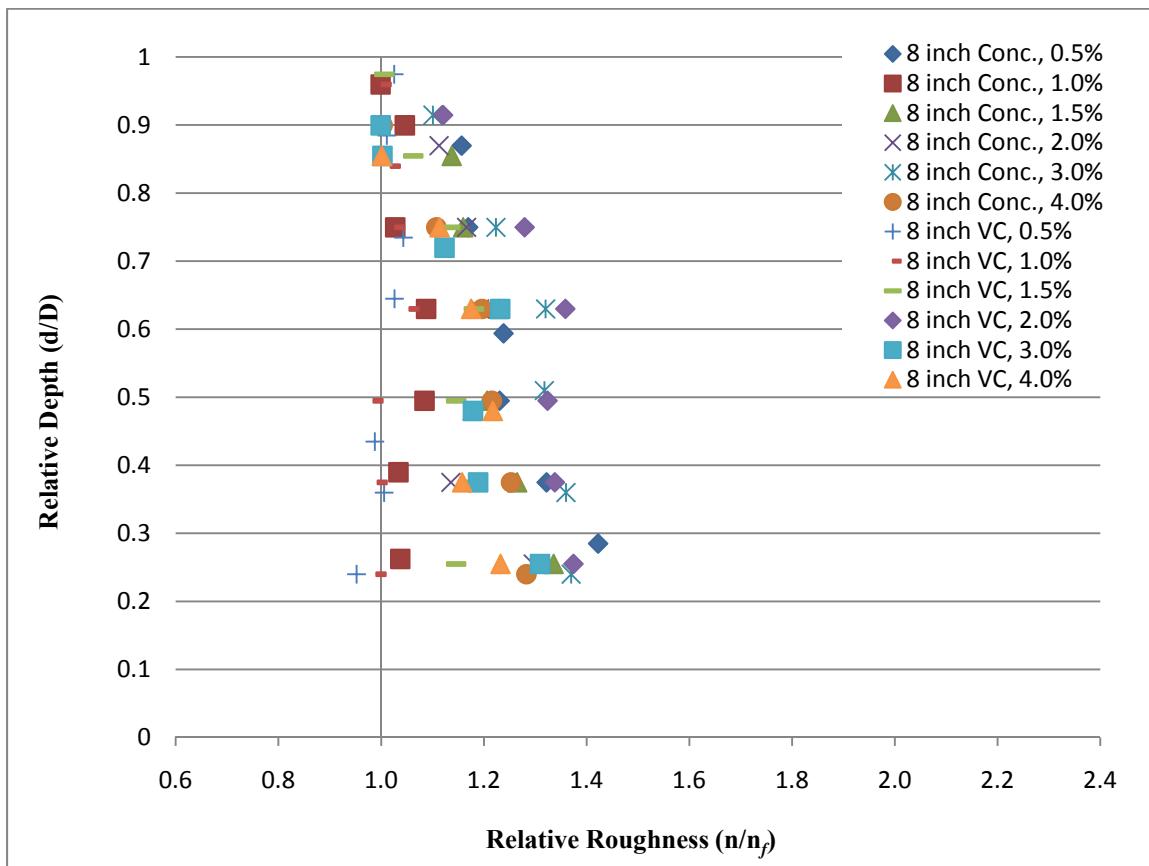

Figure 2: Experimental Data from Wilcox (1924). Data appear to have negative slope with decreasing relative depth, positive trend for 8 inch VC at 0.5% slope, no discernable trend for 8 inch concrete at 1.0% and VC at 1.0%.

2.4.3 Camp (1946)

Camp (1946) expanded the partial flow investigations of Wilcox (1924) and Yarnell and Woodward (1920) with research investigating circular sewer pipe designed to flow partially full. He emphasized that designers need quality estimates for flow and discharge fluctuations. Camp states “the hydraulic element graphs in common use have been prepared on the assumption that the roughness coefficient n does not change with the depth of flow in the conduit. It has been known for years that this assumption is erroneous, but it has been necessary to continue the use of the charts because of the lack of adequate data with which to correct them.” Camp further mentions that the works of Wilcox and Yarnell and Woodward contain data indicating pipes under partial flow exhibit Manning’s roughness values greater than at full flow. From this, Camp updated hydraulic element curves. His relative depth versus relative roughness curve is shown below as Figure 3. Camp’s curve suggests that culverts designed for partial flow using the manufacturers’ constant n have overestimated velocities.

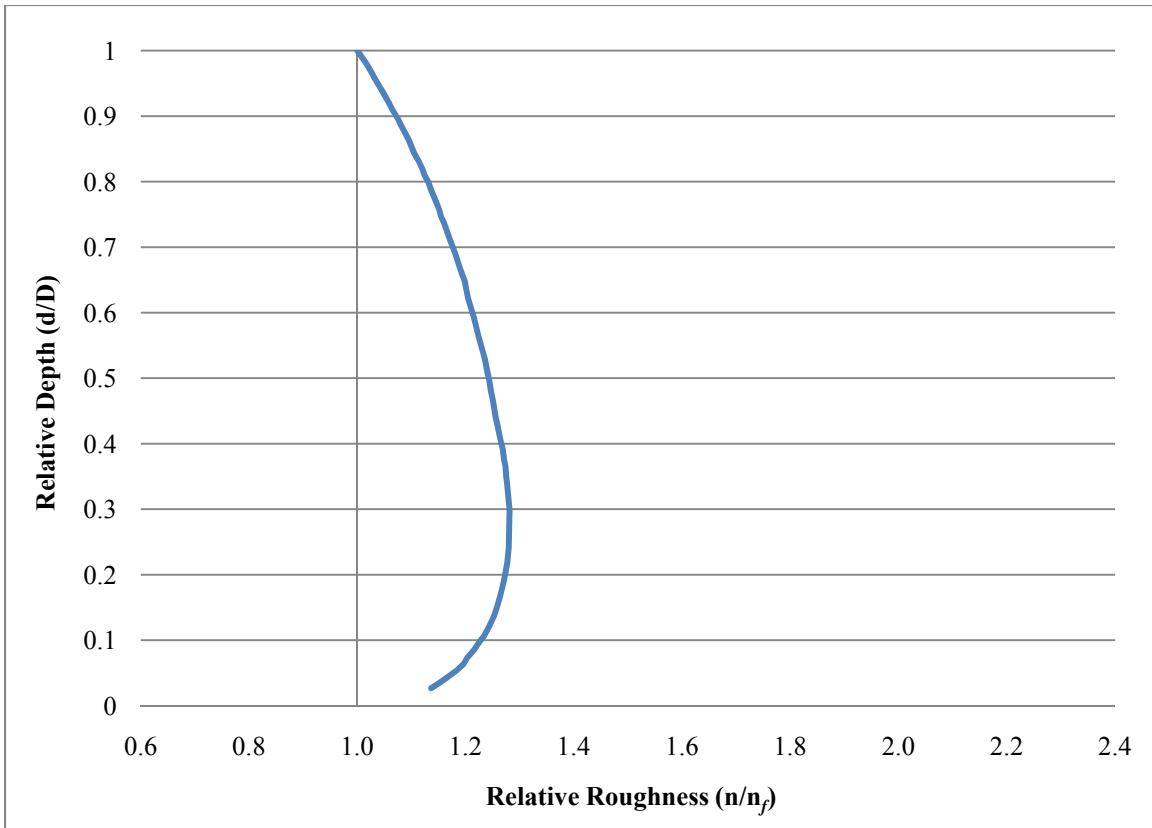

Figure 3: Hydraulic Elements Curve Developed by Camp (1946). Camp's curve indicates that partial flow roughness is larger than full flow roughness.

2.4.4 Straub and Morris (1951)

Straub and Morris (1951) researched hydraulic data on culverts comprised of 18, 24, and 36 inch diameter concrete and corrugated steel with 0.2% slope. They observed that Manning's n decreased as diameters increased for a relative depth, but that as the Reynolds number increased, so did n . From their data, seen in Figure 4, n appears to be independent of the relative depth counter to their conclusion in the text.

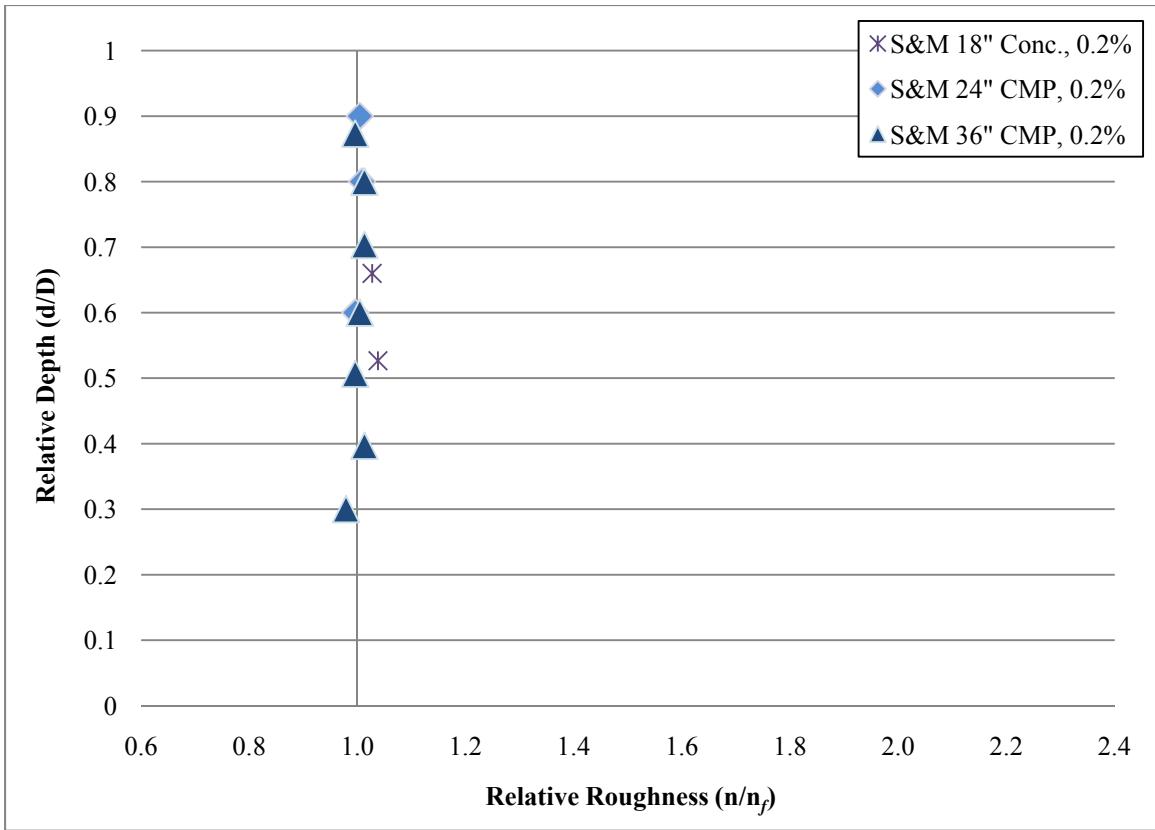

Figure 4: Experimental Data from Straub & Morris (1951). Decreasing Relative Depth does not vary Relative Roughness values.

2.4.5 Cosen(s) (1954)

Cosen(s) (1954) performed experiments using eight inch asbestos cement and vitrified clay pipe at slopes of 0.25 and 0.4%; he observed that the velocities at both half full and full were not equal for either material reinforcing the notion that Manning's n changes with depth. In addition to concluding that the roughness coefficient changes with depth of flow, he also determined that as slope of the energy grade line increases, roughness increases. This implies that under partial flow conditions both the slope of the energy grade line and low flow depths create higher n values. Cosen(s)' experimental data is illustrated in Figure 5. According to Pomeroy (1967), Cosen(s) data "are rather scattered, and appear to indicate that flows were not uniform through the test section."

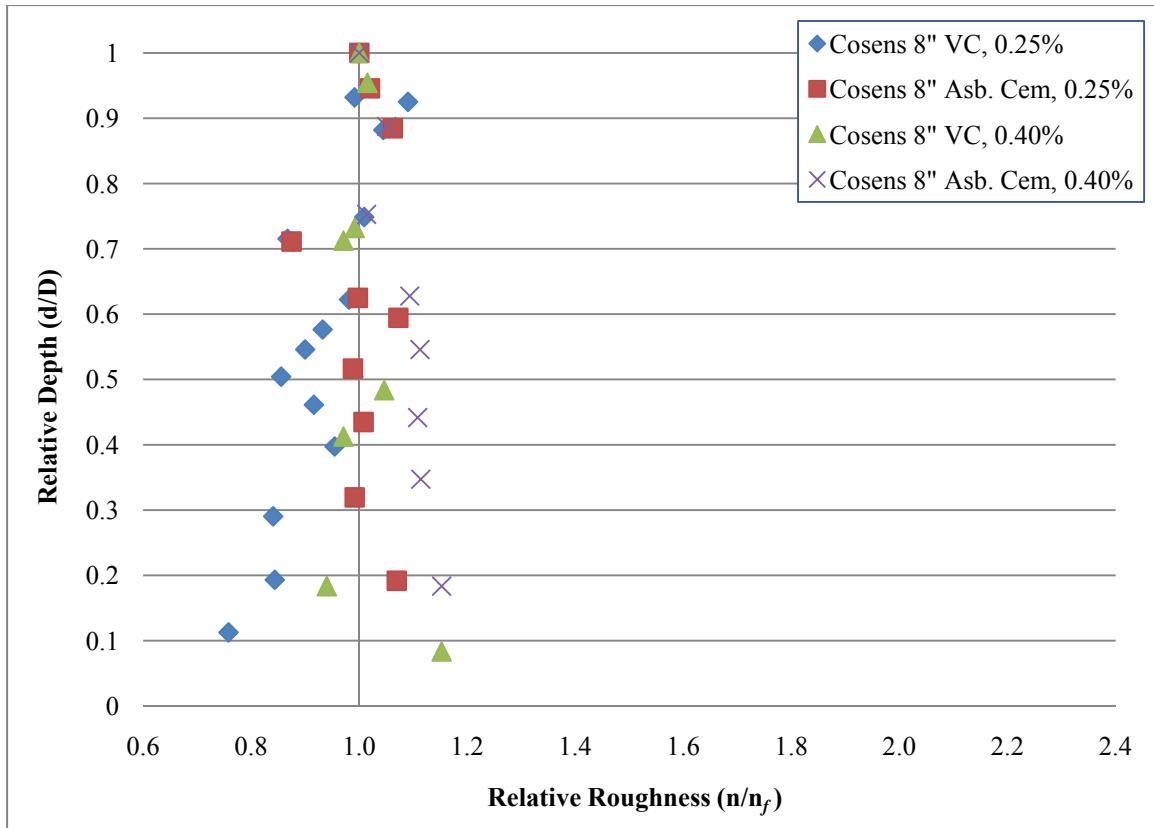

Figure 5: Experimental Data from Cossens (1954). Data appear scattered, as Relative Depth decreases Relative Roughness values do not appear to have a distinct correlation between them.

2.4.6 Neale and Price (1964)

Neale and Price (1964) experimented with eight and 12 inch polyvinyl chloride pipe (PVC) with slopes of 0.3, 0.6, and 1%, under both full and partially full flow conditions. Figure 6 illustrates that as relative depth decreases the relative roughness remains approximately constant and independent of the velocity. Another assertion was that the kinematic viscosity must be taken into account when calculating flow characteristics (Neale and Price 1964).

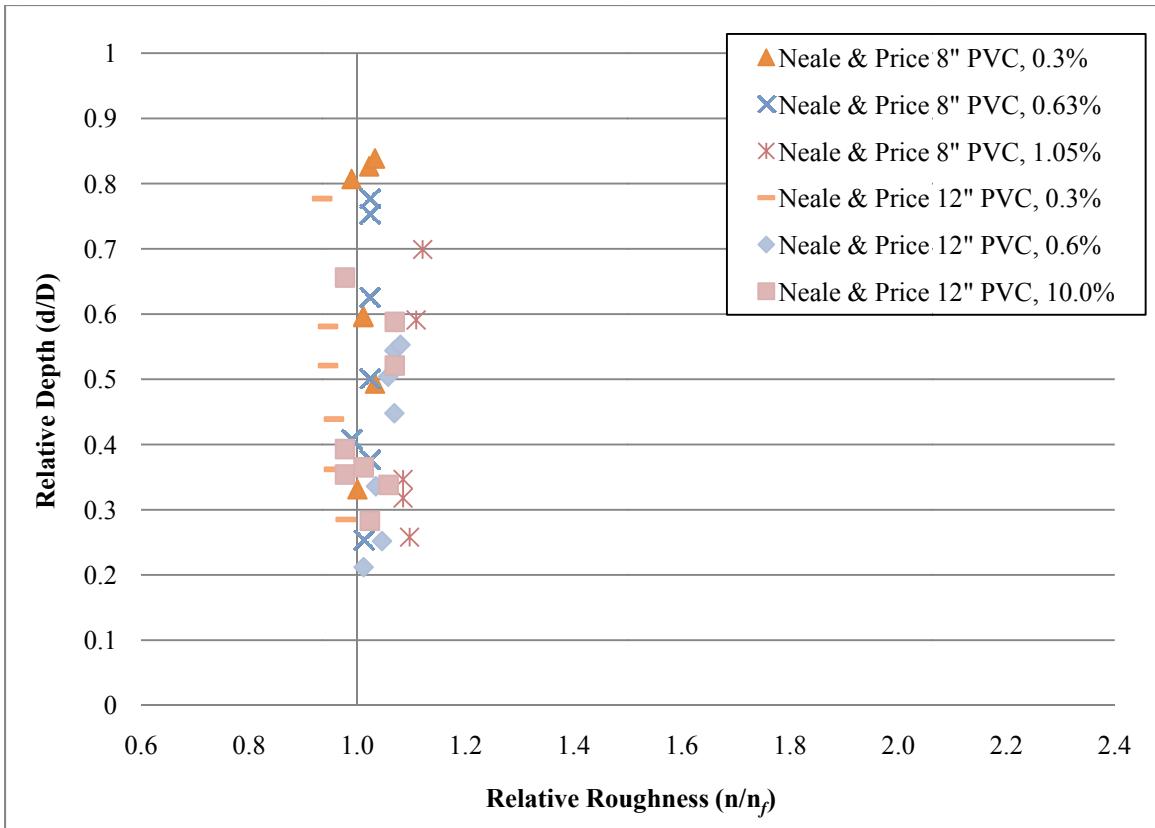

Figure 6: Experimental Data from Neale & Price (1964). Decreasing Relative Depth does not vary Relative Roughness values.

2.4.7 Pomeroy (1967)

Pomeroy (1967) examined the previous works of Wilcox, Yarnell and Woodward, Cossens, Straub and Morris, Neale and Price, and Bloodgood and Bell while researching sewers at various locations throughout the United States. The research was aimed to show that different design variables in the sewers have various hydraulic effects. He notes that velocities at low relative depths were ignored and not studied by previous research. Pomeroy asserts that “the n value is a coefficient in an empirical equation, and properly is defined as a mathematical function of the variables of the equation.” Pomeroy concludes that “the variation of n with depth should be taken into account...by correcting all n

values to a reference depth.” As a result, Pomeroy introduced a second curve to represent the variability of relative roughness which is shown in Figure 7.

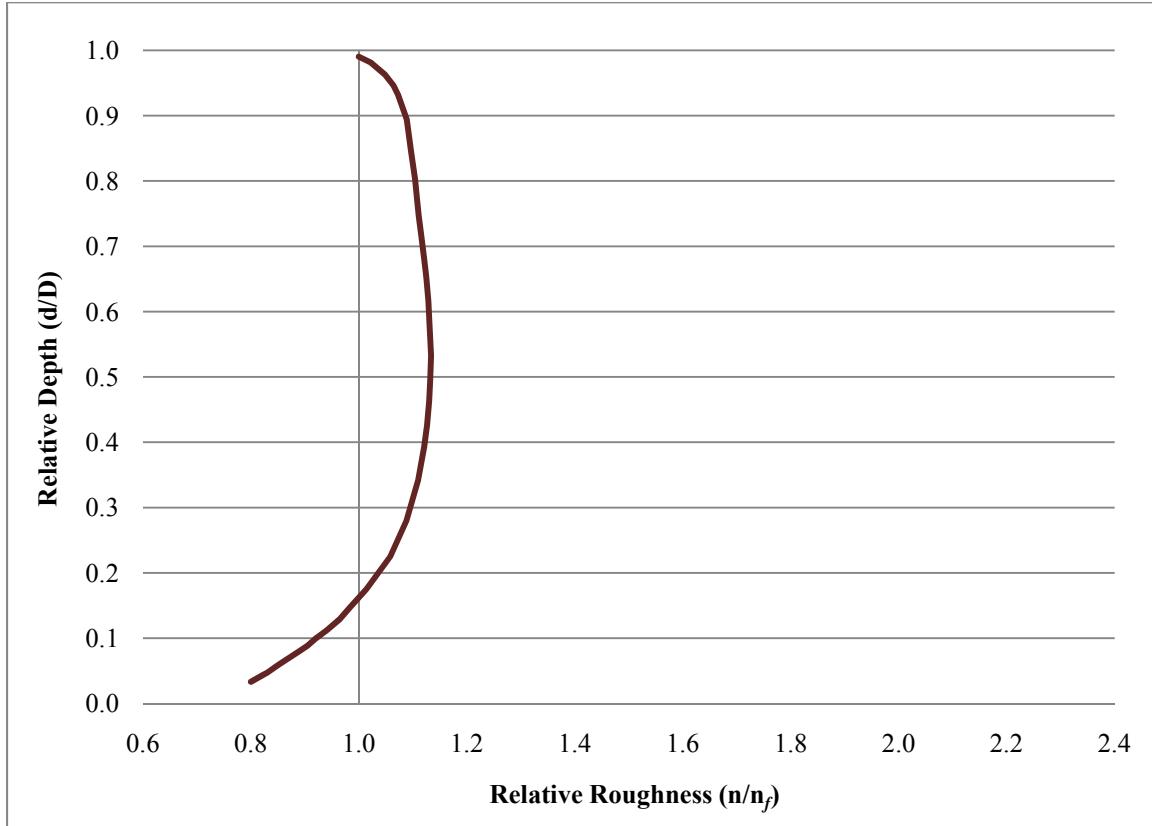

Figure 7: Hydraulic Elements Curve Developed by Pomeroy (1967). Pomeroy’s curve indicates that as relative depth decreases, the partial roughness is greater than the full flow roughness except for flows below 18% full.

2.4.8 Cox, Thornton, and Beeby (2009)

Cox *et al.* (2009) examined 36 inch HDPE pipe at slopes of 0.71%, 1.35%, and 1.97% and six different flow rates. The main purpose for the study was to determine a Manning’s coefficient value for HDPE pipe commissioned by the manufacturer. The report analyzes the data to determine an average Manning’s roughness of 0.0106 for discharges greater than 18 cfs and 0.0091 for 2 cfs in fully flowing culverts. It does not discuss how roughness varies with changes in water depth and provides no further

analysis or discussion. A plot of their data which appears to conform to Pomeroy's curve is shown in Figure 8.

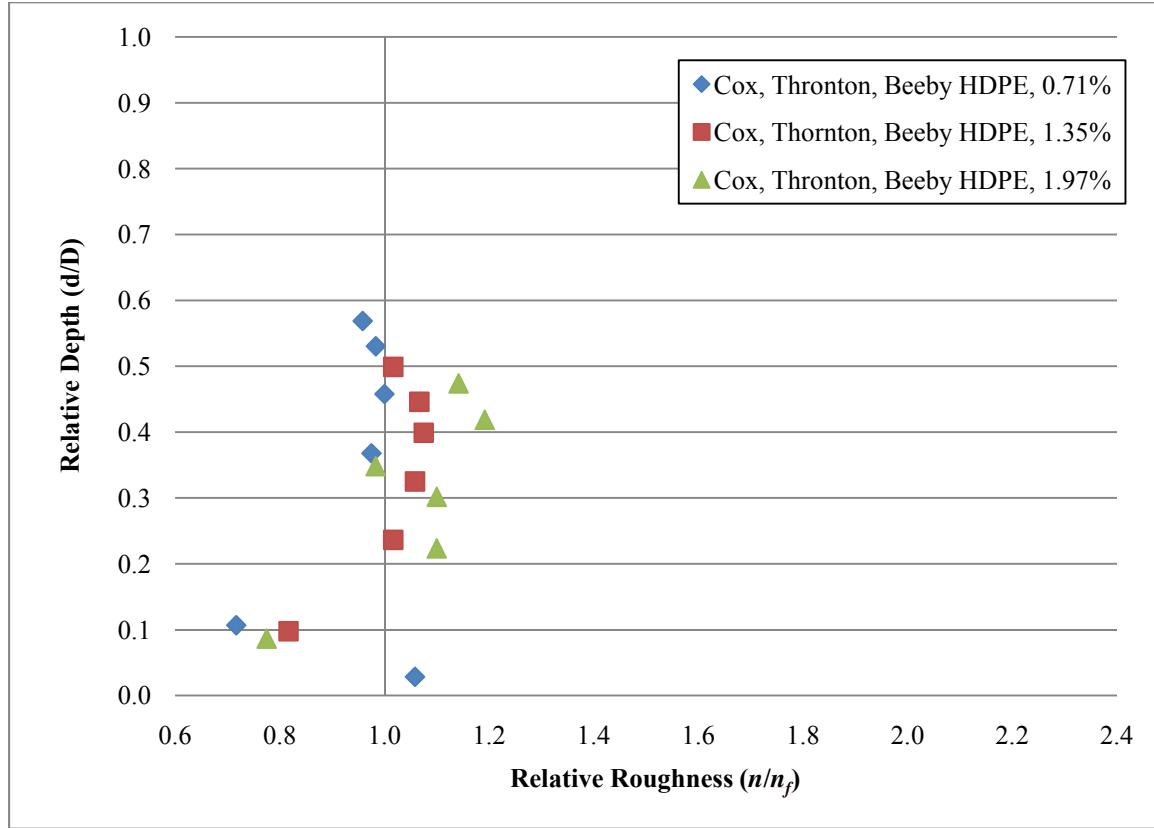

Figure 8: Experimental Data from Cox, Thornton, and Beeby (2009). Data appear to conform to Pomeroy's curve until half-depth is reached.

2.5 Examination of Investigator Data

The previous investigators collected 99% of their data at d/D values greater than 0.23 (see Figure 9). From the author's personal observations made at many culverts from May 2005 to May 2007 (approximately 2000 in total) located in northeastern Ohio, non-flood culvert flow depths were closer to a quarter full and below. The eight partial flow investigations therefore did not look at depths of flow which are more typical in culverts during non-flood stages in Ohio or similar areas.

Figure 9 shows the combined data from all the studies discussed above. Ninety-two percent of the data have a n/n_f value greater than one indicating that as depth decreases the roughness increases. Further analysis shows that as d/D decreases, the distribution of n/n_f appears to have an upper limit with a negative slope (shown on Figure 9), and the range of relative roughness values broadens; but this does not reveal why the variability in values exists. The largest distribution of n/n_f values (ranging from 0.8 to 2.3) occur at a relative depth of approximately 0.35.

Pomeroy's curve seems to be the most accurate for d/D values greater than 0.9 but Camp's curve fits the data best for $0.25 < d/D < 0.9$. It is not apparent from the data how either curve below was developed for d/D of 0.23.

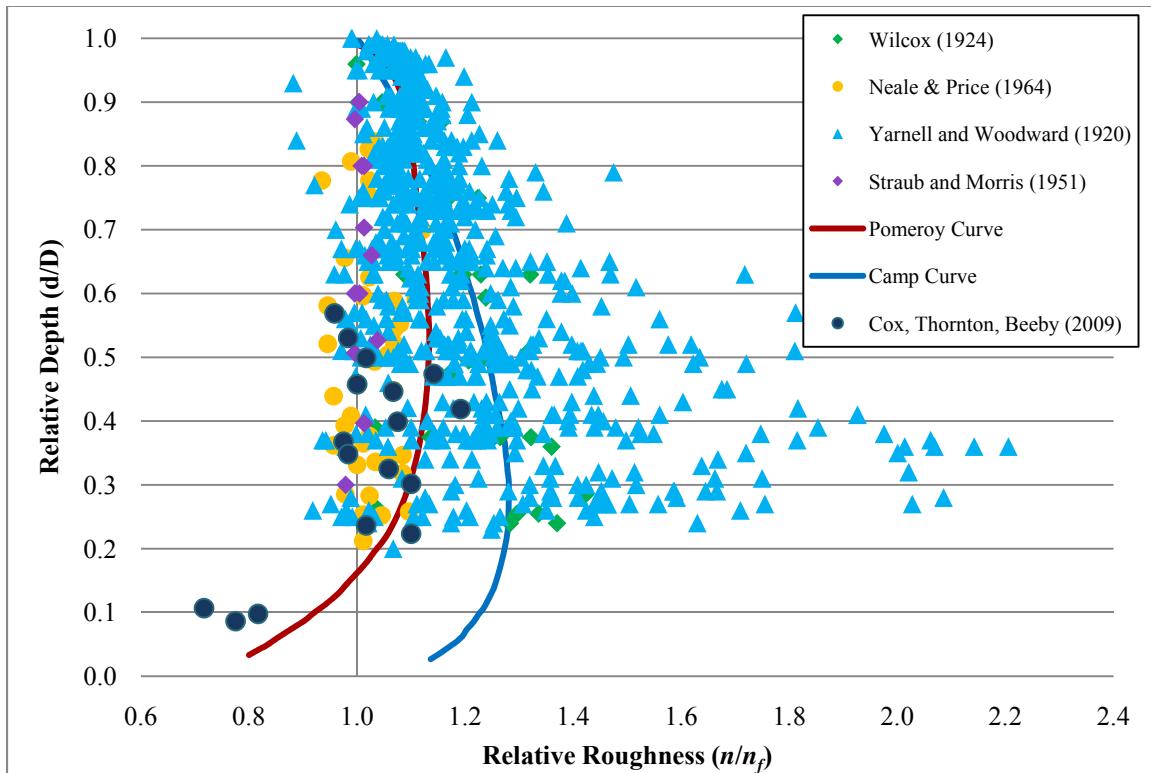

Figure 9: Combined Experimental Data. As Relative Depth decreases, measured values of partial depth roughness can be as much as 2.3 times full depth roughness.

The data were categorized into subgroups in an effort to clarify the discrepancies and identify any discernable trends. The data were grouped by investigator, material, diameter, and slope. The material data were grouped into clay, concrete, PVC, and corrugated metal graphs. The varying ranges of diameters were grouped into plots of four to six inch, eight to ten inch, twelve inch, and greater than twelve inch. The slope data were arranged by the following groups: $\leq 0.75\%$, $0.75\% < S \leq 1.5\%$, and $> 1.5\%$. Table 1 shows physical culvert parameters from each of the investigations for ease of reference. From these segregated data, no trends were apparent or the rationale for the spread in relative roughness as relative depth decreases.

Table 1: Physical Culvert Parameters from Experimental Investigations

Investigation	Slope(s) (%)	Diameter(s) (in.)	Material(s)
Woodward & Yarnell (1920)	0.05, 0.1, 0.2, 0.3, 0.5, 0.75, 1, 1.25, 1.5	4, 5, 6, 8, 10, 12	Concrete, Clay
Wilcox (1924)	0.5, 1, 1.5, 2, 3, 4	8	Concrete

Cox, Thornton, Beeby (2009)	0.71, 1.35, 1.97	36	HDPE

3.0 Methods

3.1 Manning's Roughness Variability

Pomeroy (1967) stated that Manning's n is a function of the parameters that comprise the Manning's equation and not a measure of roughness. Upon analysis of the Cosenis data, the author agrees with Pomeroy statements that the Cosenis data are scattered; therefore Cosenis data were omitted from the data set used for further analysis in this thesis.

It is therefore hypothesized that Manning's roughness is a function of discharge (Q), depth (d), diameter (D), and slope (S). In order to prove that n/n_f is a function of d/D (relationship illustrated in Figure 9); the Manning's equation at full flow was introduced devoid of new variables or parameters. First, the Manning's equation for any data point was divided by its' full flow counterpart to derive an n/n_f term, as shown in Equation 2.

$$Equation\ (2):\ \frac{Q}{Q_f} = \left(\frac{n_f}{n}\right) \left(\frac{R}{R_f}\right)^{\left(\frac{2}{3}\right)} \left(\frac{A}{A_f}\right)$$

Next, using the properties of a circle and formulae for arc-sections from Khan (1986) (which can be seen in Table 2) the values for hydraulic radius and area were expressed as a function of the angle (θ) created between the concentric center of the pipe and the water surface (Figure 10).

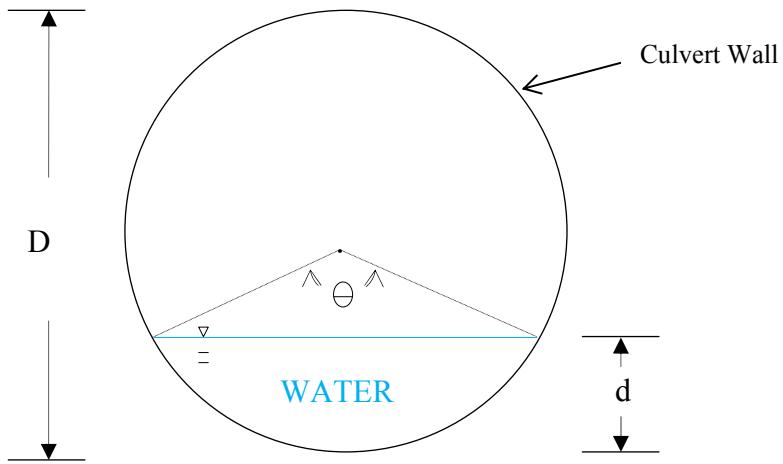

Figure 10: Defining Angle θ for a Circular Culvert Cross-Section (Khan 1986)

Table 2: Hydraulic Element Equations for Circular Cross-Sections Khan (1986)

	Area (A)	Wetted Perimeter (P)	Hydraulic Radius (R_h)
Partially Filled	$\frac{D^2}{8}(\theta - \sin \theta)$	$\frac{D}{2}\theta$	$\frac{D}{4\theta}(\theta - \sin \theta)$
Full	$\pi \frac{D^2}{4}$	$D\pi$	$\frac{D}{4}$

The angle (θ) is dependent only on the diameter of the culvert and the depth of water shown as Equation 3.

$$\text{Equation (3): } \theta = 2 \cos^{-1} \left(1 - 2 \frac{d}{D} \right)$$

Inserting the appropriate equations for hydraulic radius and area into Equation 2 yields a simplified equation (Equation 4, derivation shown in Appendix K) that expresses the relative roughness as a function of the relative depth and relative discharge (Q/Q_f).

$$\text{Equation (4): } \left(\frac{Q}{Q_f} \right) \left(\frac{n}{n_f} \right) = \left(1 - \frac{\sin \theta}{\theta} \right)^{\left(\frac{2}{3} \right)} \left(\frac{\theta - \sin \theta}{2\pi} \right)$$

When the data from previous investigations are plotted such that relative depth is a function of the product of the relative discharge and the relative Manning's n (Figure 11), rather than simply the Manning's n (Figure 9), the data appear less scattered and indicating a higher percentage of the variance is captured. A trend line (shown in pink) has been added showing the prediction from Equation 5.

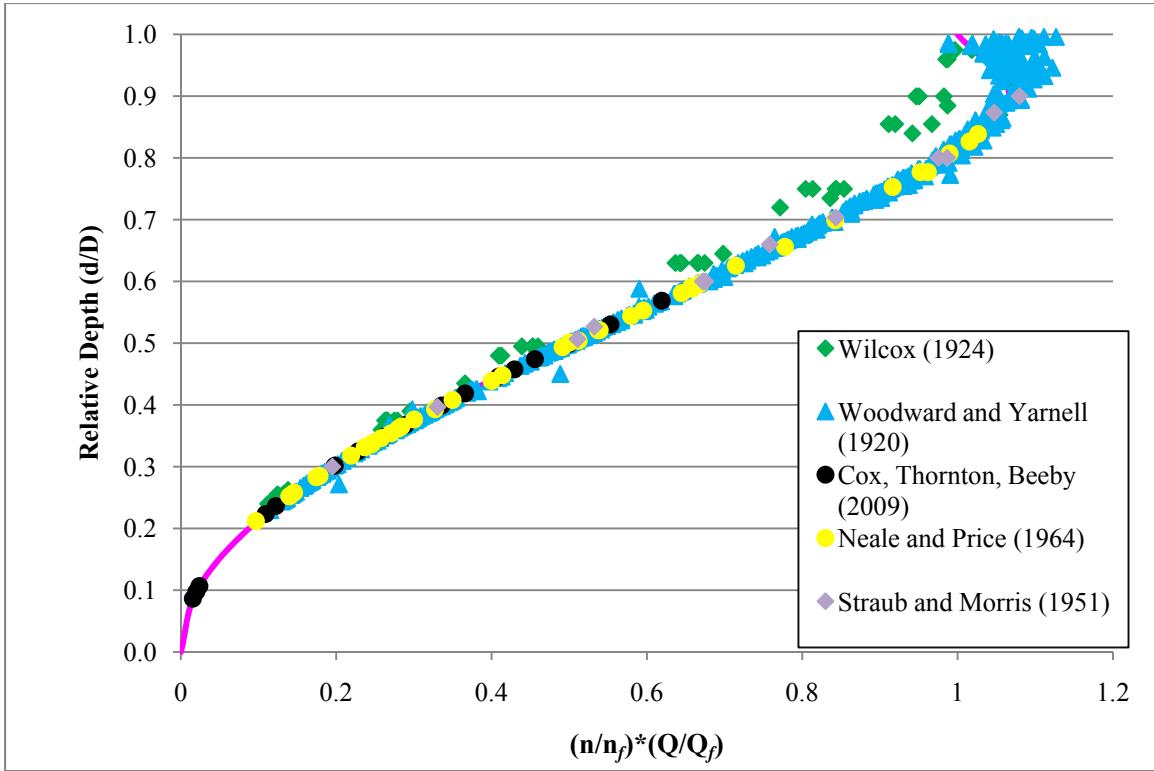

Figure 11: Reducing the Spread of Investigator Data. The data from the five partial flow investigations fit the trend-line from Equation 5 with minimal spread indicating that the variance in Manning's n is simply a function of both the relative depth and the relative discharge.

For a typical design problem two unknowns exist (depth and Manning's n) with only one equation (Equation 5). In order to rectify this problem a second equation is necessary. This equation would need to either relate Manning's n to depth or relate discharge to depth independently from Manning's n . The method used to solve the problem in this study was to develop an equation independent from Manning's equation.

3.2 Depth Equation

In order to accurately predict the depth, an equation relating depth and discharge was needed. In researching texts an independent equation from the Manning's equation for partially filled culverts was not found. Such an equation must be valid across all data sets therefore; the equation must be dimensionally homogeneous.

3.2.1 Equation Components

It is hypothesized that the water depth (d) in a culvert is a function of discharge (Q), slope (S), diameter (D), gravity (g), and a pipe roughness value. The absolute roughness coefficient (K_s) was included to account for material type because it is not dependent on flow depth. Instead, absolute roughness is only a function of material because when any material is viewed microscopically, projections can be seen (Khan 1986). Absolute roughness, which has units of length, is a measure of the height of these projections (Khan 1986). Absolute roughness differs from Manning's n (which has units of time/length^{1/3}) because K_s is a physically measurable constant; whereas, Manning's n is an empirical variable that accounts for other information in addition to roughness (Pomeroy 1967).

3.2.2 Equation Development

In order to reduce the number of independent variables (and therefore the complexity in determining the appropriate depth-discharge relation), the Buckingham Pi Theorem was utilized. According to Khan (1986), if there are x variables with y dimensions to a physical problem, then the quantities can be arranged into x minus y

dimensionless parameters representing the problem. The depth discharge relationship has six variables and two dimensions (length and time); therefore, there are four independent dimensionless parameters that define the system shown as π 's below (The derivation of the variables into dimensionless parameters is shown in Appendix J).

$$\pi_1 = \frac{Q}{\sqrt{gD^5}} \quad \pi_2 = S \quad \pi_3 = \frac{K_s}{D} \quad \pi_4 = \frac{d}{D}$$

The relative depth is therefore a function of three dimensionless parameters:

$$\frac{d}{D} = f\left(\frac{Q}{\sqrt{gD^5}}, \frac{K_s}{D}, S\right)$$

From these three dimensionless variables it was assumed that the equation followed a power law shown in Equation 5.

$$Equation\ (5):\ \frac{d}{D} = h \left[\frac{Q}{\sqrt{gD^5}} \right]^a \left[\frac{K_s}{D} \right]^b [S]^c + j$$

In order to solve for the exponents (a, b, c) and constants (h and j), each of the dimensionless variables was calculated. The data were then sorted by the three dimensionless variables. The first dimensionless variable was plotted against the observed d/D holding the other two variables constant to obtain exponent a . This process was then repeated for the second and third variables to obtain their exponents. The highest R^2 value of 0.95 occurred when a equaled 1, b equaled 1/6, c equaled -1/2, h equal to 0.32, and j equal to 0.2 (Figure 12). These exponents allow the equation to account for 95% of the variance associated within the data set.

Grouping of discharge, gravity, and diameter as π_1 has been previously performed by Vasconcelos and Wright (2005) as a non-dimensional flow rate (Q^*), shown as Equation 6. That term was substituted into the equation resulting in Equation 7.

$$Equation (6): \quad Q^* = \frac{Q}{\sqrt{gD^5}}$$

$$Equation (7): \quad \frac{d}{D} = (0.32) \left(\frac{Q^*}{\sqrt{S_o}} \right) \left(\frac{K_s}{D} \right)^{\frac{1}{6}}$$

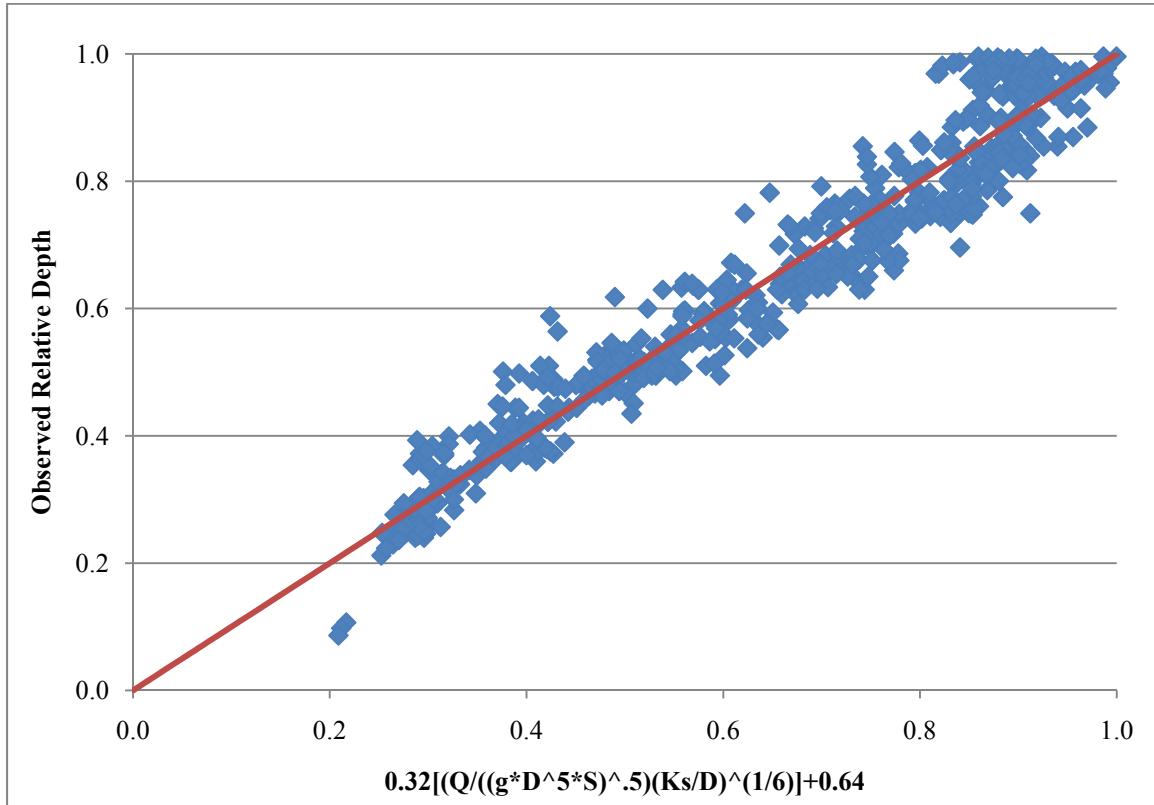

Figure 12: Exponent Development Graph for New Equation

3.2.3 Final Depth Equation

The best fit linear regression obtained from Figure 12 resulted in establishing the final Depth Predictor Equation (Equation 8).

$$Equation (8): \quad d = .32D \left[\left(\frac{Q^*}{\sqrt{S_o}} \right) \left(\frac{K_s}{D} \right)^{\frac{1}{6}} + 0.64 \right]$$

3.3 Conversion of Chezy C to Manning's *n*

The Chezy C value, obtained from Yarnell and Woodward (1920), has been converted to Manning's *n* values using Equation 9(Mays 2005); where (*n*) is Manning's roughness coefficient, (R) is the hydraulic radius, and (C) is the Chezy C.

$$\text{Equation (9):} \quad n = \frac{1.486}{C} (R)^{\frac{1}{6}}$$

3.4 Obtaining *n* Values for Manning's Equation

The predicted depth based on Manning's equation was accomplished using two versions of the roughness coefficient *n* - the manufacturers' suggested value for each material type and The Ohio Department of Transportations' (ODOT) Location and Design Volume 2 (2010) design value of 0.013. The manufacturers' roughness coefficient *n* values in the calculations were 0.011 for concrete from the American Concrete Pipe Institute (ACPA 2000), 0.013 for clay pipe from the National Clay Pipe Institute (NCPI 2006), 0.012 for PVC from Uni-Bell (Uni-Bell 2001), 0.024 for CMP from the National Corrugated Steel Pipe Institute (NCSPIA 1999), and 0.012 for HDPE from ADS-Hancor (ADS-Hancor 2010).

3.5 Solving Manning's Equation

Excel's Goal-Seek function combined with the Macros written by Samuel R. Mangin (2010) (shown in Appendix I) were used to solve for the predicted water depth for each data point in the data set using Manning's equation.

3.6 Statistical Analysis for Significance

A test for significance compares observed data to predicted data (Moore and McCabe 2003). A measure of how well the observed data and the predicted data agree is expressed in terms of a probability (p-value) (Moore and McCabe 2003). The statement being tested is called the null hypothesis. The test of significance assesses the strength of evidence against the null hypothesis (Moore and McCabe 2003). When the p-value is less than α , the level of significance chosen, the alternative hypothesis is true (Moore and McCabe 2003).

The test of significance used in this thesis is paired student *t*-test. The null hypothesis considered is that Manning's equation and the newly developed equation have equal error when predicting the depth in partially-filled circular culverts. The alternative hypothesis is that the new equation and the Manning's equation do not equally predict depths.

Paired student *t*-tests were performed on the depth predictions calculated by the new equation and the Manning's equation. The threshold of 0.05(α) was set as the mark for statistical significance, and a 0.10 threshold for moderate statistical significance. Five hundred fourteen data points were analyzed for the Manning's equation that did not include the erroneous predictions (discussed in Section 4.3). A total of 722 data points were analyzed for the Manning's equation that had the 208 lines of the erroneous data's d/D set equal to one. The new equation had the identical data points tested for both versions of the Manning's equation, with and without the erroneous data.

4.0 Results and Discussion

Equation 8 was developed to predict depth in a circular culvert, similar to that of the Manning's equation. In order for this new equation to be an improvement on the Manning's equation it needs to have a greater predictive power for water depth. The dimensionless parameters that were developed through the Buckingham Pi Theorem to predict depth in Equation 8 were not surprising because of the similarities found in other equations. As previously stated, the Q^* term has been reported before by Vasconcelos and Wright (2005) as a non-dimensional flow rate. The absolute roughness term is one of the dimensionless terms in the Moody Diagram (Chow 1959) and the exponent of 1/6 appears regularly in depth-discharge equations and in the Manning-Strickler Equation (Chanson 1999). The slope term to the 1/2 power is also found in many fluid equations such as the Chezy Equation (Chow 1959).

The data evaluated for this study date from the 1920's through the late 2000's, and the methods of measurement have changed over time with technological advances in instrumentation. While all of the data is secondary data (not collected by the author), the data are believed to be valid. As illustrated in Figure 11, the observed data are consistent with the theoretical trend-line with very minimal spread and outliers. The data are from different decades, with different methods of measurement, spanning different materials, slopes, and diameters but still conform to the theory presented for Equation 4.

4.1 Determining Depth using Manning's Equation

For a given discharge (Q), Manning's roughness (n), slope (S), and diameter (D), a solution for depth (d) in a partially filled culvert cannot be found explicitly. A direct

solution for depth (d) is not possible because depth is embedded within theta (θ) which is embedded within the hydraulic radius (R_h) and area (A).

4.1.1 Manning's Equation with Manufacturer Suggested n -Value

The Manning's equation using manufacturer suggested n values erroneously predicted the culvert to be greater than full depth for 23.8%, 172 of the data points. These data were not plotted. The data that predicted a partial depth were graphed and are shown in Figure 13 (See Appendix C for data).

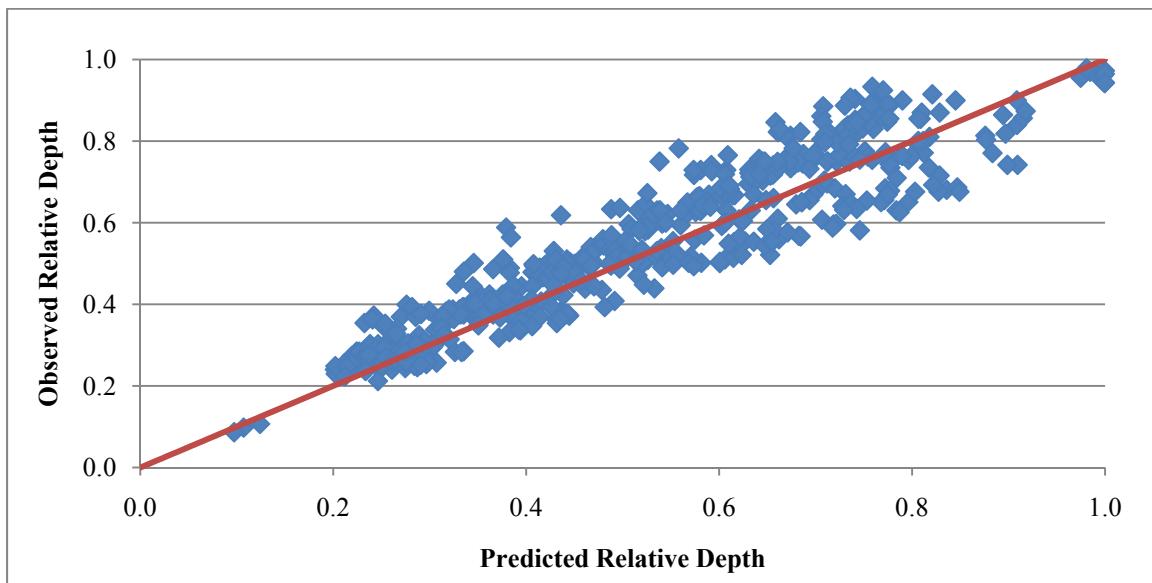

Figure 13: Depth Prediction (Manufacturer Suggested n Value). Cases in which greater than full depth was predicted are not plotted, representing 23.8% of the data set.

4.1.2 Manning's Equation ODOT Design n Value

The depth was determined utilizing the design n values from ODOT's Location and Design Volume 2 (2010). It was found that in 208 (28.8% of the data) Manning's equation erroneously predicted the depth to be greater than full. These data were not

plotted. The data points where a partial depth was predicted were graphed and are shown in Figure 14 (See Appendix D for data).

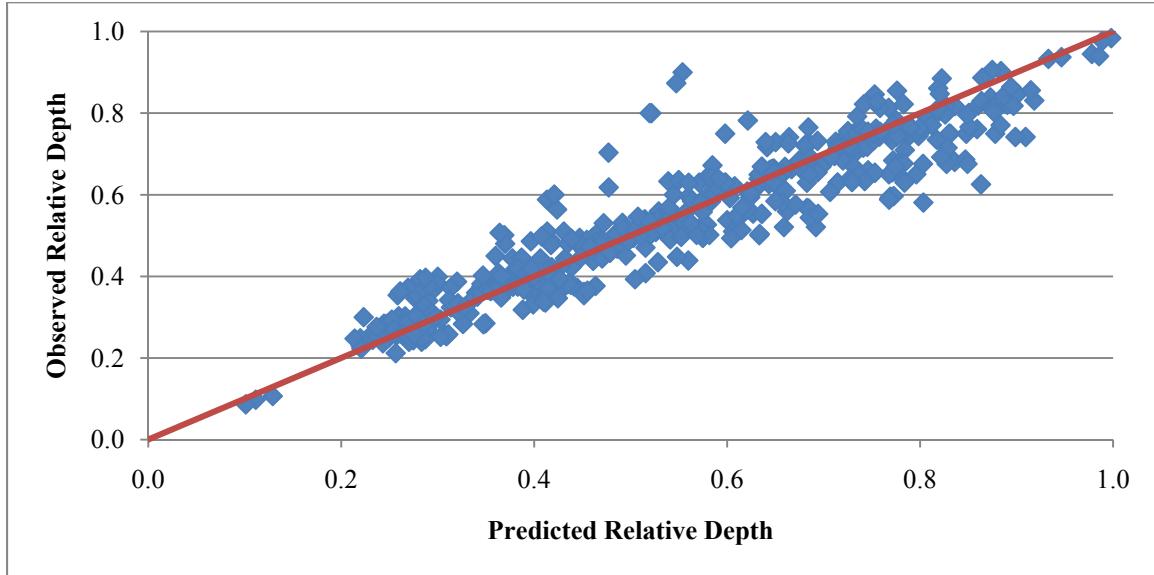

Figure 14: Depth Prediction (Design n Value 0.013). Cases in which greater than full depth was predicted are not plotted, representing 28.8% of the data set.

4.2 New Equation Prediction

The absolute roughness term varies by material (Chow 1959). The reported K_s values for concrete are 0.01-0.001 (Chow 1959), 0.0005 for clay (CPDA 1999), 0.0417 for CMP (Khan 1986), 0.000005 for PVC (Uni-Bell 2001), and 0.00005 for HDPE (PPI 2008). An average K_s value of 0.0055 was used for concrete in the Average K_s scenario; concrete K_s value of 0.01 and adjusted K_s values for PVC and HDPE were used in the “best fit” case.

It can be seen from Figure 15 that there are different lines for each material indicating that the published K_s values should be adjusted for partially filled culvert conditions. Due to these multiple lines, a power law regression has a slightly higher R² value equal to 0.90 than the linear regression (R² equal to 0.85).

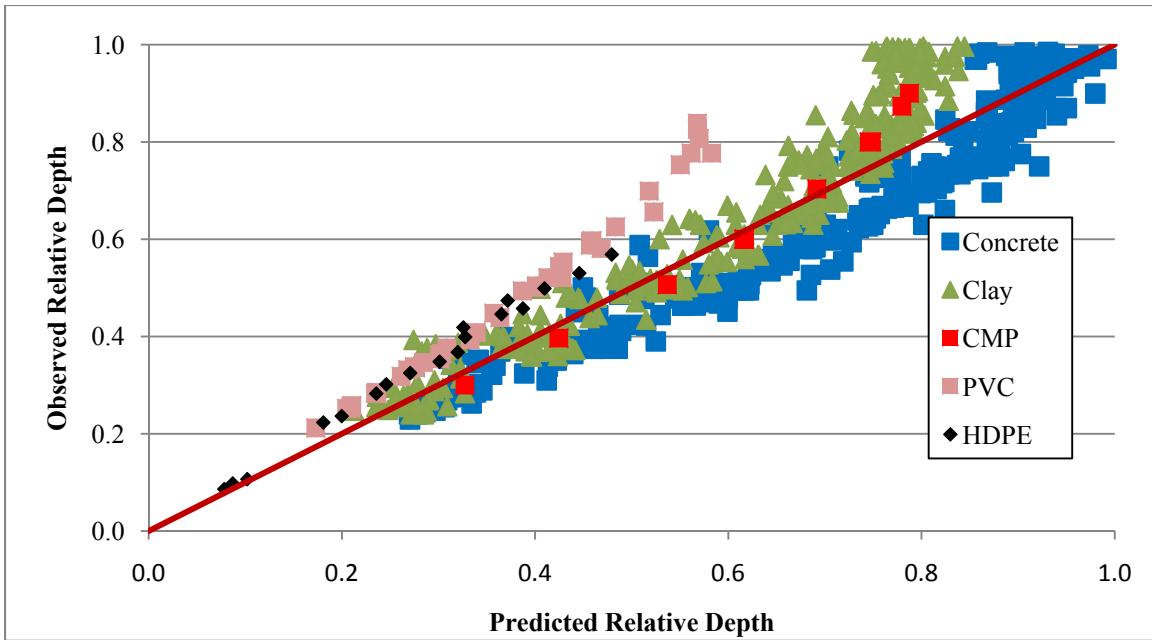

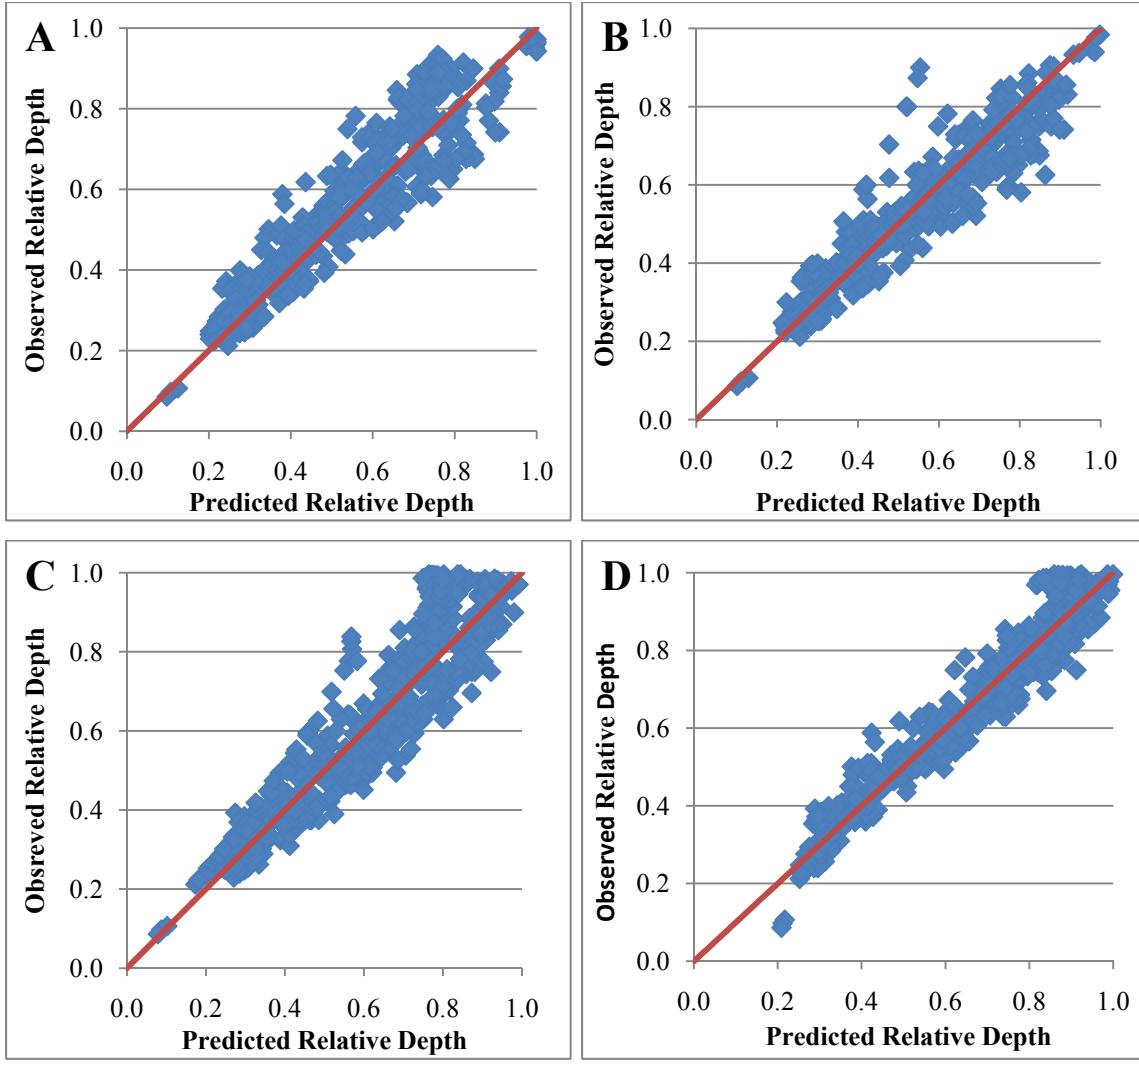

Figure 15: Depth Prediction New Equation (Average Ks Value). Multiples lines can be seen from grouping data by material. This indicates that the published relative roughness values are incorrect for partially filled circular culverts.

To further collapse the data and reduce the spread from the average Ks graph, adjusted Ks values for PVC and HDPE were used. Both of these materials' values were changed one order of magnitude larger, from 0.00005 for HDPE to 0.0005. Concrete's maximum Ks value of 0.01 was used. The data was then graphed and is shown in Figure 12 (See Appendix F for data).

4.3 Comparison of Equations

To allow the reader easier referencing and comparison, Figures 10-13 have been re-plotted as Figure 16. A comparison of the average of the absolute value of the percent error from the observed depth for the Manufacturers' Suggested n Values (see Appendix G for data), ODOT Design n Values, average Ks Equation (see Appendix H for data) did not indicate any significant difference (paired student t-test, $p < 0.05$) in the predictive

capacity of the three equations. However, the adjusted Ks version of the new equation performed significantly better than the other three. The following section compares the adjusted Ks Value equation to the best performing Manning's equation (ODOT Design *n* Values).

LEGEND		Mean % Error			
A	Manufacturer n Value	11.7 (10.7)	C	Average K_s	11.3 (11.1, 11.6)
B	ODOT Design n Value	8.4 (10.9)	D	Adjusted K_s	6.9 (7.11, 7.4)

Figure 16: Depth Prediction Comparison. All four graphs show apparent outliers in the bottom left portion of the graph. Graph A and B appear to have greater spread than graph D. Graph C appears to have multiple lines of data. The data in the tables are represented in different colors. The black values are the mean percent error for the entire data set consisting of 722 data points. The purple values represent the mean percent error for comparison between 550 data points for the manufacturer suggested n value. The red values are the mean percent error for the 514 data points compared for the ODOT design n value.

The new equation allows for the explicit solution of depth while the Manning's equation produces an implicit solution that is iterative. The iterative solver (Excel GoalSeek) did not find a viable solution for depth in 29% or 208 lines of data. The reason for this is that the solution began to converge to a relative depth greater than one – such a depth is not a physical possibility in the Manning's equation, so a final solution was not produced. The solutions from Manning's equation that erroneously predicted depths greater than full depth were not initially included in the analysis of error. The Manning's equation prediction for depth had an average error of 10.9% compared to observed depths. The depth was also predicted using the same data points with the new equation having adjusted K_s values. The mean percent error was 7.4%. According to the paired student t-test shown as Table 3, the results were moderately significant with a probability of 0.078 (0.05 < p < 0.10); therefore, the null hypothesis was accepted (see Section 3.6).

Table 3: Paired t-Test: Paired Two Sample for Means, Manning's ODOT Design n Value and Adjusted K_s Value Equation. Depths where Manning's does not converge are not included.

	<i>Manning's Equation - ODOT Design n Values</i>	<i>New Equation - Adjusted K_s Values</i>
Mean % Error	10.85	7.38
Observations	514	514
P(T<=t) two-tail	0.078	

Upon further analysis, it is apparent that the iterative sequence utilized by the Goal-Seek function in Excel to numerically solve for depth is terminated when a value larger than full depth is reached. In an effort to account for the erroneous data, where the

observed depths were near full, a d/D value of 1 for the 208 lines was assumed and the data was statistically analyzed again (results shown in Table 4).

The new equation with the adjusted Ks values and the Manning's equation with ODOT Design *n* Values were found to have mean percent errors of 6.9% and 8.4% respectively. From Table 4 the mean percent error for Manning's equation decreased. This decrease was because the data initially not included in the analysis were from observations where the pipe was flowing near full depth (d/D greater than or equal to 0.9). The new equation predicted depth significantly better than the Manning's equation when all data are included. Due to the p-value ($p = 4.66E-6$), the null hypothesis was rejected and statistically the predictions are not equivalent. The mean percent error is reduced 18% when utilizing the new equation. As illustrated in Figure 16, the spread for graph D is less than that of graph B indicating that the new equation is more precise for a 1:1 relationship between relative depth and relative roughness. Due to this information, it can be concluded that the new equation performs best as a depth predictor in partially filled circular culverts.

Table 4: Paired t-Test: Paired Two Sample for Means, Manning's ODOT Design *n* Value and Adjusted Ks Value Equation. All Data included, Divergent Data now with $d/D = 1$

<i>Manning's Equation - ODOT Design n Values</i>	<i>New Equation - Adjusted Ks Values</i>
Mean % Error	8.38
Observations	722
P($T \leq t$) two-tail	4.66E-06

4.4 Manning's n Equivalence

To calculate an n value, the design engineer would solve the Manning's equation for roughness, Equation 1; but, two unknowns exist, n and depth (depth is embedded in the hydraulic radius and area). The goal of this research was to develop a new equation (Equation 8) to predict depth, but if the design engineer is more comfortable using Manning's equation, the new equation allows a solution for n in Equation 1 without the design engineer choosing full flow n values. By combining Equations 1 and 8, Equation 10 can be used to determine an appropriate n for partially filled culverts. Equation 10 is a function of theta (θ), which now takes the form shown in Equation 11.

$$Equation \ (10): \quad n = \frac{1.486 \left[\left(\frac{D}{4\theta} \right) (\theta - \sin \theta) \right]^{\frac{2}{3}} \left[\frac{D^2}{8} (\theta - \sin \theta) \right] (S)^{\frac{1}{2}}}{Q}$$

Equation (11):

$$\theta = 2 \cos^{-1} \left[1 - 2 \left(0.32 \left(\left(\frac{Q_i^*}{\sqrt{S_o}} \right) \left(\frac{Ks}{D} \right)^{\frac{1}{6}} + 0.64 \right) \right) \right]$$

5.0 Conclusion

In the design of a culvert for fish passage, knowing the depth is important because if the depth is too shallow a passage barrier is created. Also once discharge and depth are known, the velocity can be calculated which may also be a passage barrier. The current method for predicting depth, (Manning's equation with constant n), results in an average of 10.9% error between predicted and observed depths. If the designer is using roughness coefficients for full flow a substantial error in depth could result. However, guidelines currently do not exist for adjusting n values for partially filled culverts.

The equation developed in this thesis predicts depth independently from the Manning's equation and Manning's n . In comparison with predictions from the Manning's equation, the new equation with the Adjusted K_s values performs better. For instance, Manning's equation predicts water depth 70% of the time with a mean error of 10.9%, whereas the new equation predicts depths for the entire data set with a mean error of 6.9%.

This thesis has found that Manning's n does vary with depth. In fact, it varies with both relative depth and relative discharge. The new equation which is independent of Manning's n performs better than the Manning's equation. Based on this outcome a new equation for predicting Manning's n in partially filled culverts based on the new equation for depth prediction is proposed.

5.1 Recommendations for Future Research

A number of future research questions have emerged as a result of this study. Future research directions should focus on the addition of water properties that affect flow and the regression used to compare relative depth to relative roughness. It is possible that kinematic viscosity, a property of water based on temperature, should be included into the new equation; however, the existing data do not allow the investigation into that possibility. The viscosity of the water changes with temperature, possibly adding hydraulic roughness to the culvert when experiencing colder weather. In the future, adding this variable may improve predictive capabilities of depth in partially filled culverts. If viscosity is included in the Buckingham Pi Theorem, the fifth Pi would be the Reynolds Number. According to Chisholm and Tsang (1970) and mentioned by Straub and Morris (1951), Manning's n increases with the size of the conduit and that effect is more prominent for lower Reynolds numbers.

Another recommendation for future work is research into the effects of culvert aging on roughness. During the design life for a culvert, possible changes to the circumferential profile may result. According to Tullis *et al.* (2005), "hydraulic roughness is typically influenced by both the roughness of the pipe material and the pipe inside wall profile." Tullis *et al.* (2005) studied one type of HDPE, but the effect on roughness for other HDPE diameters and other materials such CMP, may need further investigation. It is also known from Bland *et al.* (1978) that the effect of sliming on the walls due to age and water conditions, changes the roughness value. It is possible that current design practices are for the "best case scenario"; meaning that as culverts age, roughness values

increase resulting in higher depths and lower velocities. Further research is suggested for roughness variations due to age.

It is apparent from the investigative data that depths below 25% of the diameter were not researched. Data at these low flows is desirable. Data at low flow depths are important because these maybe the conditions typical that a fish will encounter during its life cycle; and therefore, needs to investigated.

In order to increase the predictive capacity of the new equation for future research, it is believed that a linear trend-line regression does not accurately portray the data for $d/D < 0.2$ and $d/D > 0.9$. It is theorized that the trend-line should appear more closely to what is shown in Figure 16.

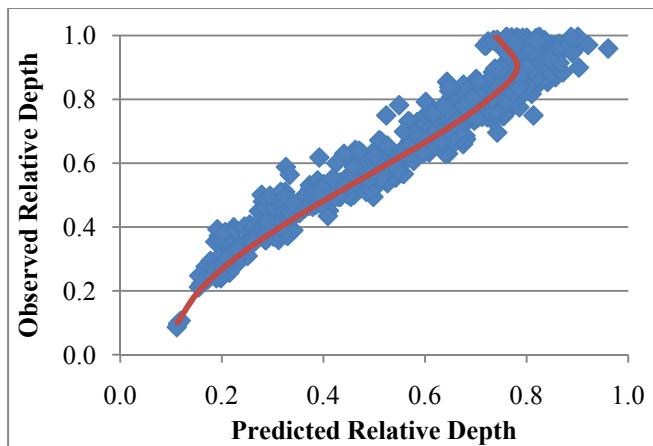

Figure 17: Depth Prediction Alternative Trend-line for New Equation
Trend-line based on Equation 5

The trend-line in Figure 16 incorporates hydraulic radius and area into the new equation thereby allowing the two ends of the curve to arc with the data. If such a trend-line exists, the depth predictive capacity of the new equation could further strengthen a 1:1 relationship between the measured depth and predicted depth. This needs to be investigated further.

Appendix I: Goal Seek Macros Program

```

Sub multiGoal()
    Dim i As Integer
    'Change the value for i below for the rows, this would be
    'row 2 to row 723.
    For i = 2 To 723
        'Change the (i,7) to (i,"COLUMN W/FORMULA") and then change
        '("F" & "" & i) to blank column for result like "DK"
        'Ok = Cells(i, 7).GoalSeek(goal:=0.25, ChangingCell:=Range("F" & "" & i))
        'Ok = Cells(i, 7).GoalSeek(goal:=Cells(i, 11), ChangingCell:=Range("F" & "" & i))
        Ok = Range("G" & i).GoalSeek(goal:=Range("K" & i), ChangingCell:=Range("F" &
i))
        If Ok <> True Then
            MsgBox ("GoalSeek() for row " & i & " did not complete successfully!")
        End If
    Next i
End Sub

```

Appendix J: Buckingham Pi Theorem Derivation

$$\begin{aligned}\pi_1 &= QDg = (L^3T^{-1})^a(L)^b(LT^{-2}) = L^0T^0 \\ L: \quad &3a + b + 1 = 0 \\ &-6b + b + 1 = 0 \\ &b = \frac{1}{5} \\ T: \quad &-a - 2 = 0 \\ &a = -2\end{aligned}$$

$$\therefore \pi_1 = \frac{Q}{\sqrt{gD^5}}$$

$$\begin{aligned}\pi_2 &= QDS = (L^3T^{-1})^a(L)^b(L^0) = L^0T^0 \\ L: \quad &3a + b = 0 \\ &b = 0 \\ T: \quad &-a = 0\end{aligned}$$

$$\therefore \pi_2 = S$$

$$\begin{aligned}\pi_3 &= QDK_s = (L^3T^{-1})^a(L)^b(L) = L^0T^0 \\ L: \quad &3a + b + 1 = 0 \\ &b + 1 = 0 \\ &b = -1 \\ T: \quad &-a = 0\end{aligned}$$

$$\therefore \pi_3 = \frac{K_s}{D}$$

$$\begin{aligned}\pi_4 &= QDd = (L^3T^{-1})^a(L)^b(L) = L^0T^0 \\ L: \quad &3a + b + 1 = 0 \\ &b + 1 = 0 \\ &b = -1 \\ T: \quad &-a = 0\end{aligned}$$

$$\therefore \pi_4 = \frac{d}{D}$$

Appendix K: Derivation of Equation 4

Step 1: Divide Partial Manning's by Full Manning's (The slopes and constants cancel)

$$Step 1: \frac{Q}{Q_f} = \left(\frac{n_f}{n}\right) \left(\frac{R}{R_f}\right)^{\left(\frac{2}{3}\right)} \left(\frac{A}{A_f}\right)$$

Step 2: Insert Equations from Table 2 for Hydraulic Radius and Area (Full and Partial)

$$Step 2: \frac{Q}{Q_f} = \left(\frac{n_f}{n}\right) \left[\frac{\frac{D}{4\theta}(\theta - \sin \theta)}{\frac{D}{4}} \right]^{\left(\frac{2}{3}\right)} \left[\frac{\frac{D^2}{8}(\theta - \sin \theta)}{\frac{\pi D^2}{4}} \right]$$

Step 3: Simplify

$$Step 3: \left(\frac{Q}{Q_f}\right) \left(\frac{n}{n_f}\right) = \left[\frac{(\theta - \sin \theta)}{\theta} \right]^{\left(\frac{2}{3}\right)} \left[\frac{(\theta - \sin \theta)}{2\pi} \right]$$

Step 4: Simplify

$$Step 4: \left(\frac{Q}{Q_f}\right) \left(\frac{n}{n_f}\right) = \left(1 - \frac{\sin \theta}{\theta}\right)^{\left(\frac{2}{3}\right)} \left(\frac{\theta - \sin \theta}{2\pi}\right)$$
